
The carbon cycle in ACCESS-ESM1

Model description and Pre-Industrial Simulation

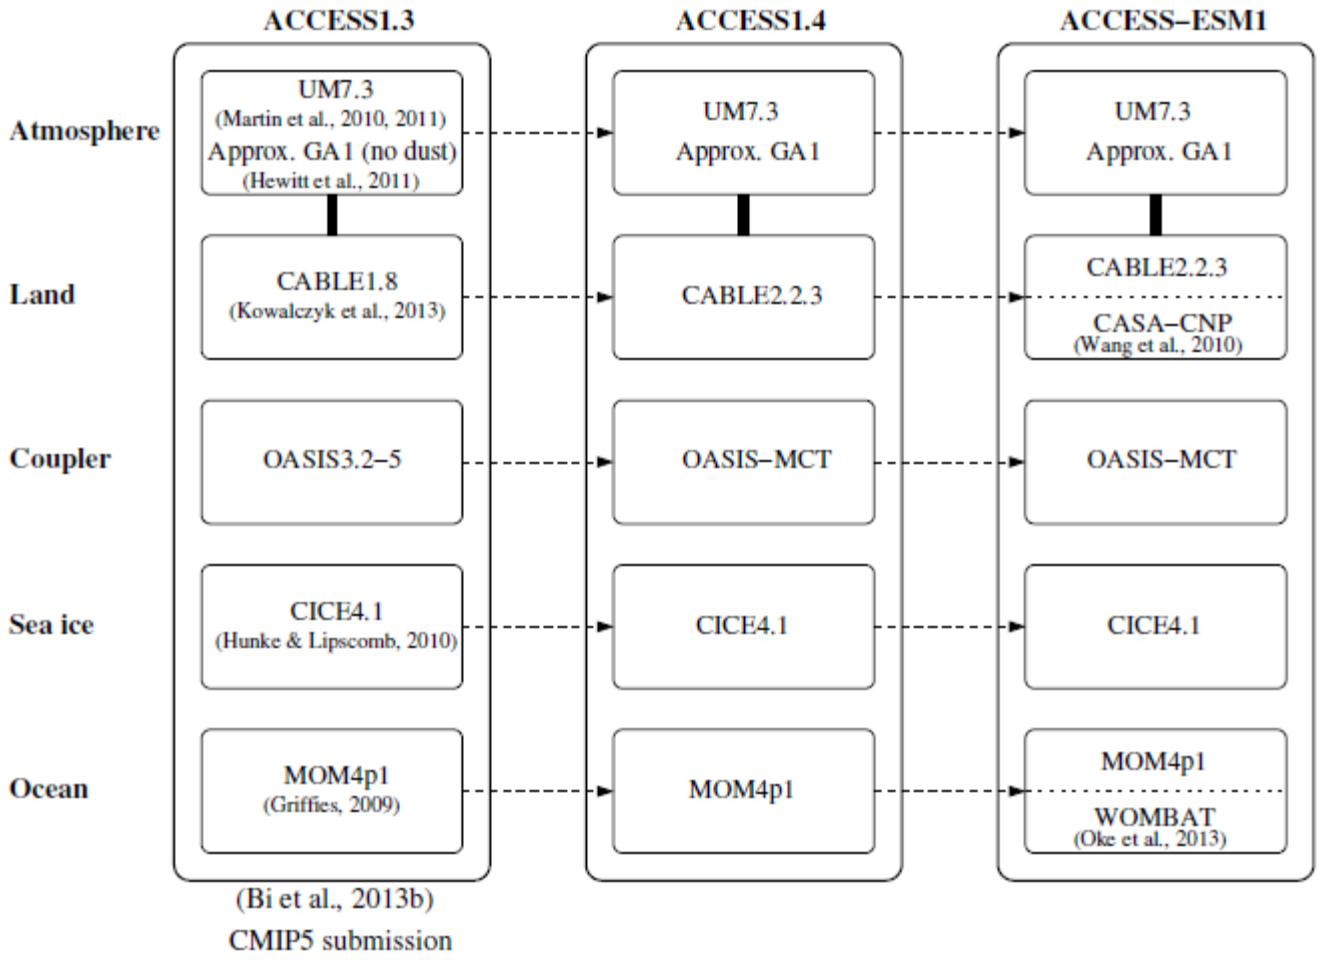
Vohralik, The carbon cycle in the Australian Community Climate and Earth System Simulator (ACCESS-ESM1). 1. Model description and pre-industrial simulation, submitted to Geoscientific Model Development.
- Revision based on editorial comments before discussions phase
- Proposed ACCESS special issue (open-ended).

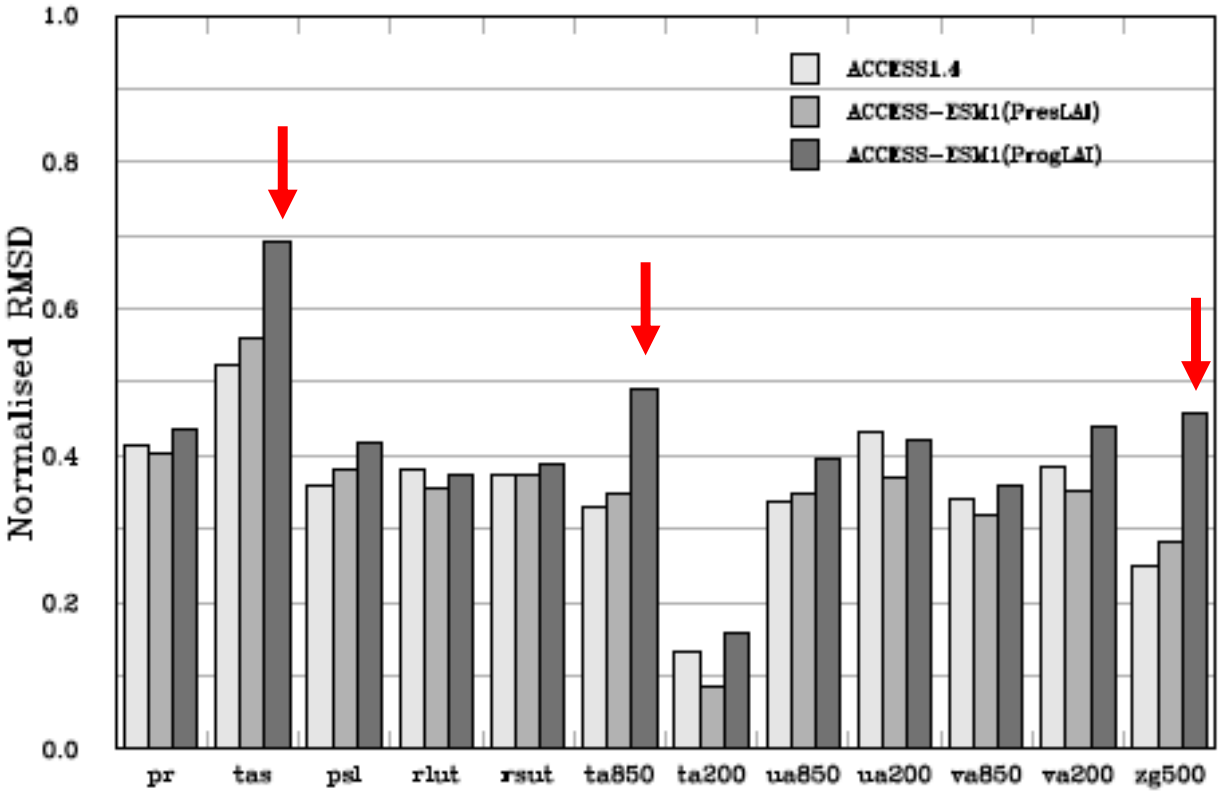
ACCESS versions



ACCESS-ESM1

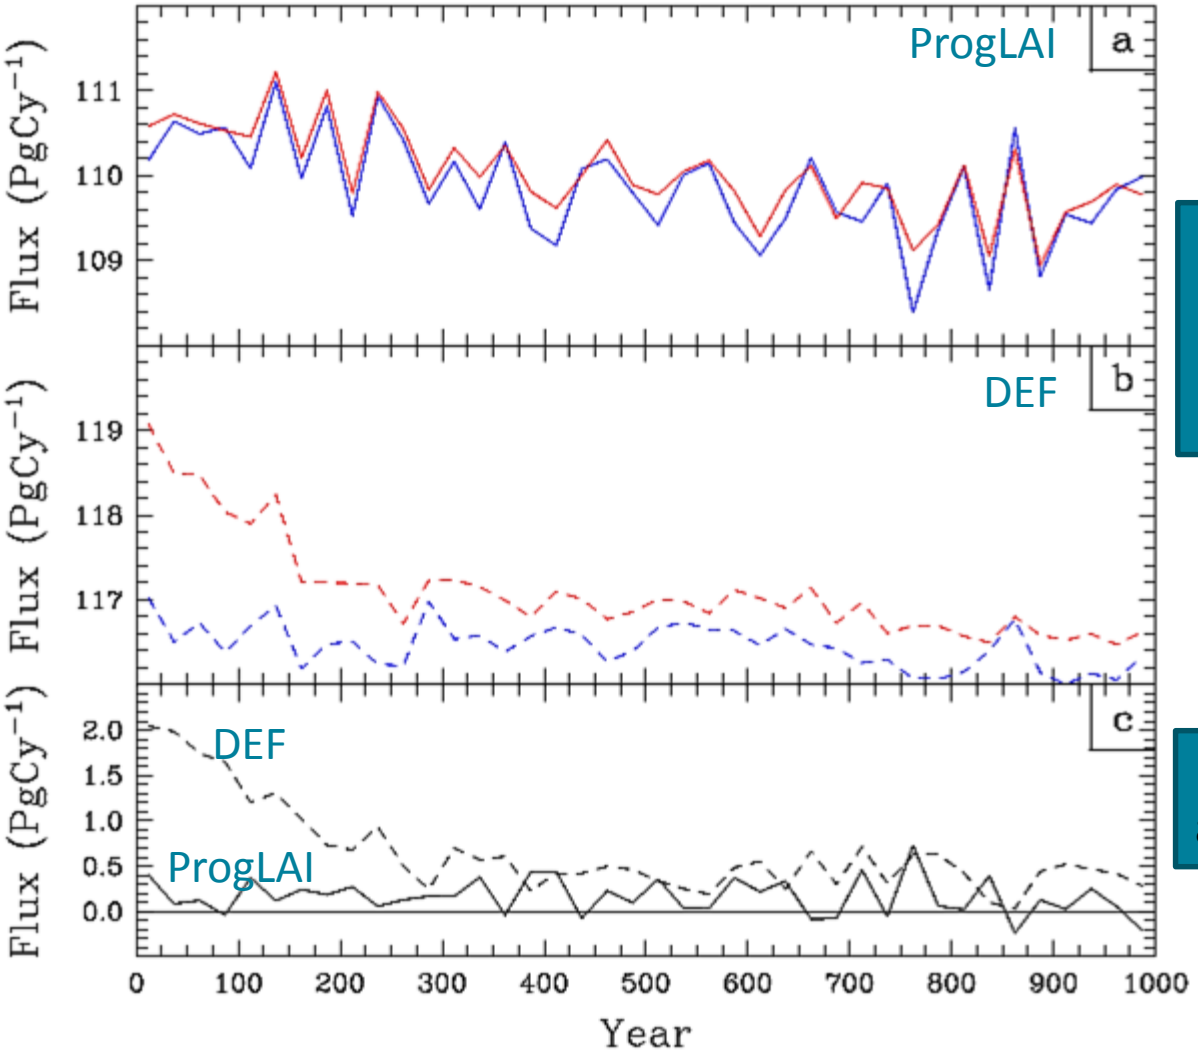
- ACCESS1.4
  - UM7.3 (~GA1.0)
  - MOM4p1
  - CABLE2.2.3
  - CICE4.1
  - OASIS-MCT
- ACCESS-ESM1
  - CABLE2.2.3 with l_casacnp=.TRUE., icycle=3 (CNP)
  - WOMBAT for ocean carbon
- Pre-industrial simulations
  - DEF – default, prescribed leaf area index, standard ocean carbon parameters
    - 1000 years
  - ProgLAI – prognostic leaf area index
    - 1000 years
    - Slight warming of climate (TAS 14.59±0.11 compared to 14.22±0.10°C)
  - AltOCN – alternate ocean carbon parameters (and numerically stable WOMBAT)
    - 500 years

Physical climate



Root mean square difference from ACCESS1.3 simulation normalized by the ACCESS1.0 to ACCESS1.3 difference.

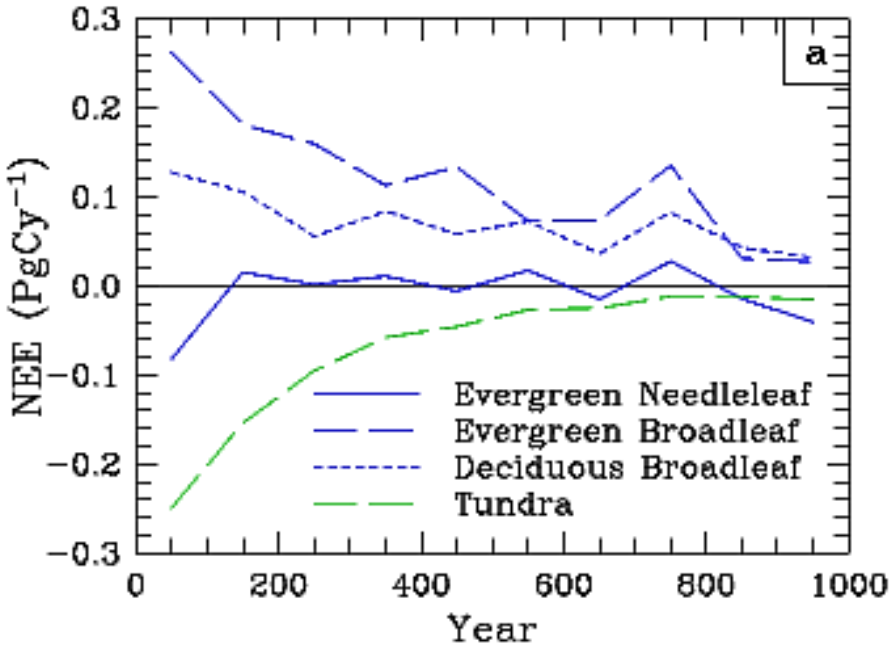
Land flux equilibration

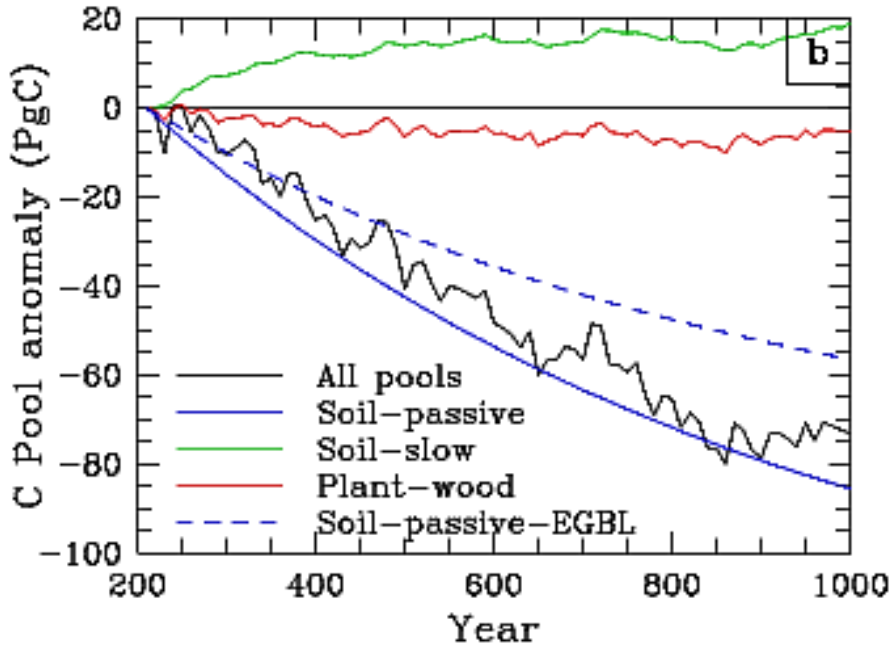


Blue – GPP (photosynthesis)
Red – total respiration

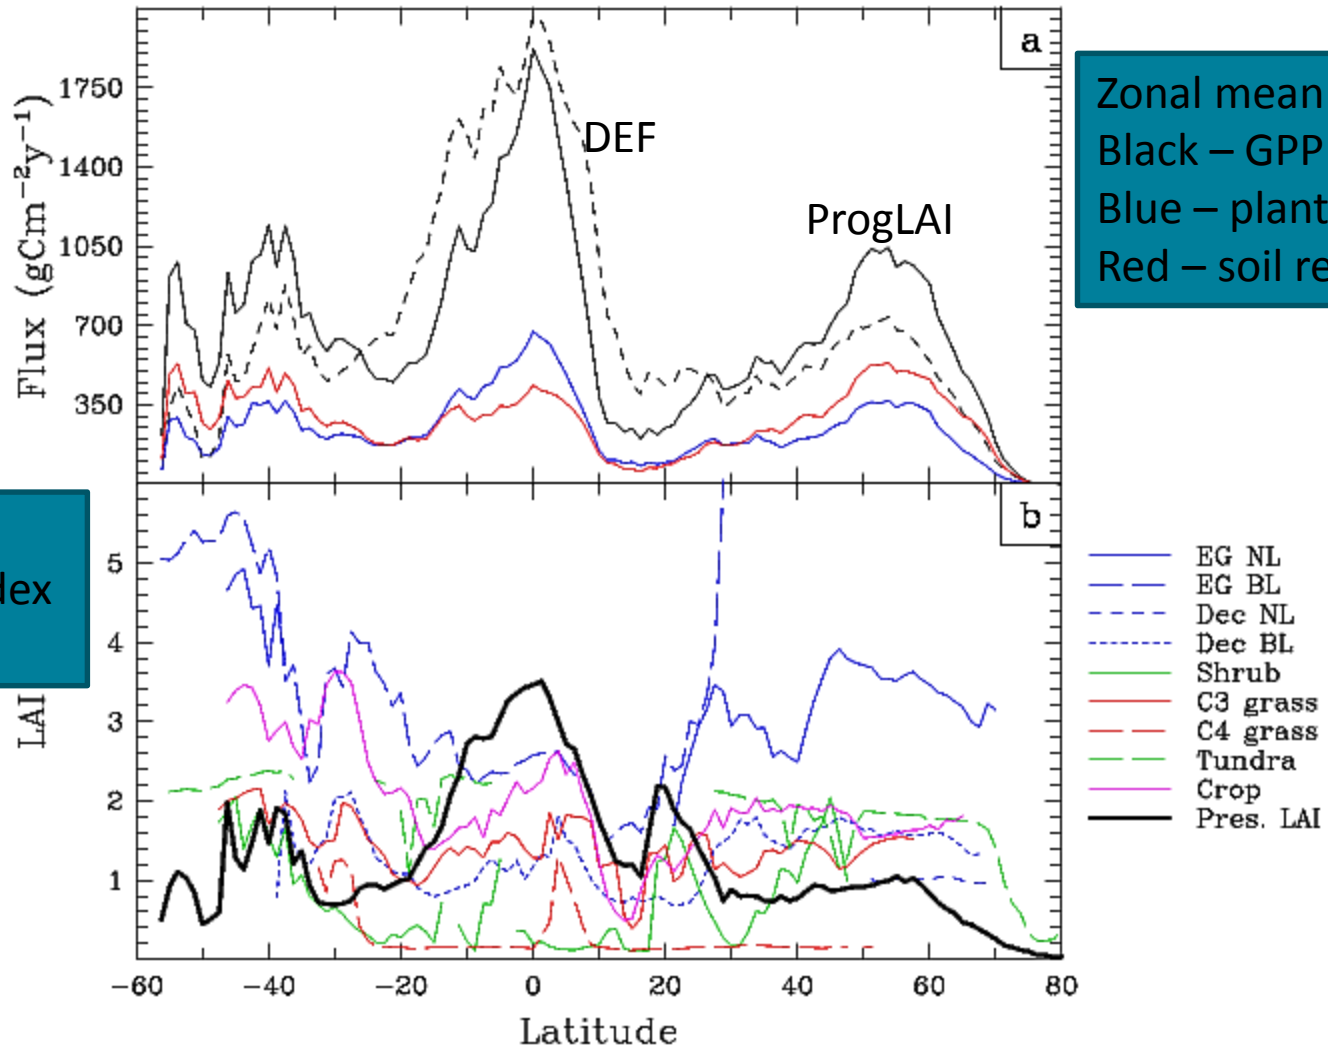
NEE – flux to atmosphere

Land flux and carbon pools - ProgLAI





Land carbon flux distribution and LAI



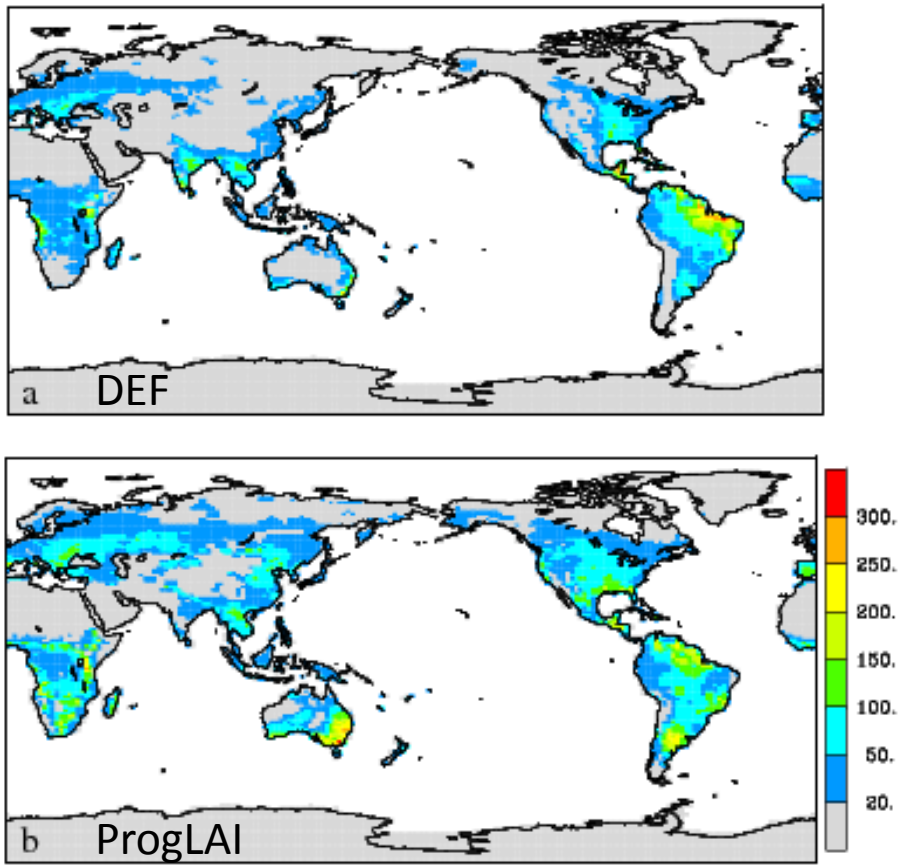
Zonal mean – land only
Black – GPP
Blue – plant respiration
Red – soil respiration

Zonal mean
Leaf Area Index
– land only

Interannual variability

	DEF	ProgLAI
GPP	1.17	1.87
Leaf Resp	0.26	0.75
Plant Resp	0.17	0.27
Soil Resp	0.27	0.32
NEE	1.40	1.21

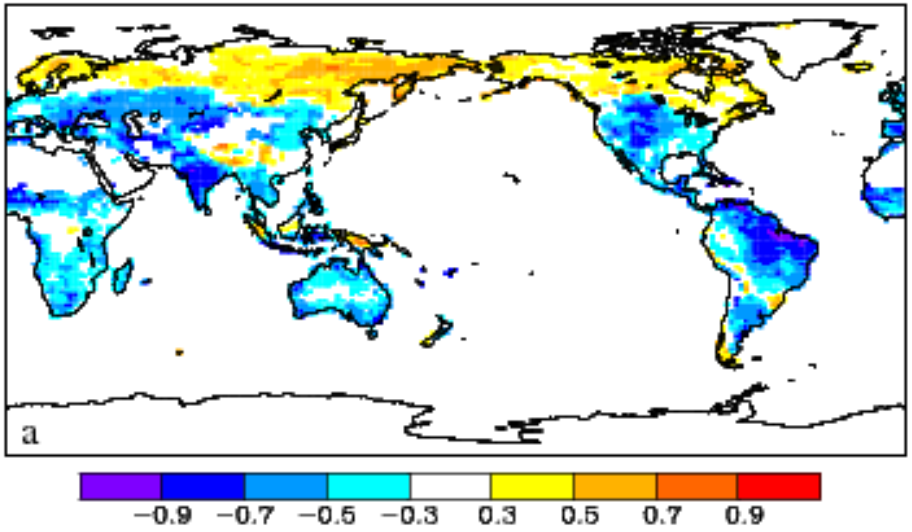
NEE standard deviation ($gCm^{-2}y^{-1}$)



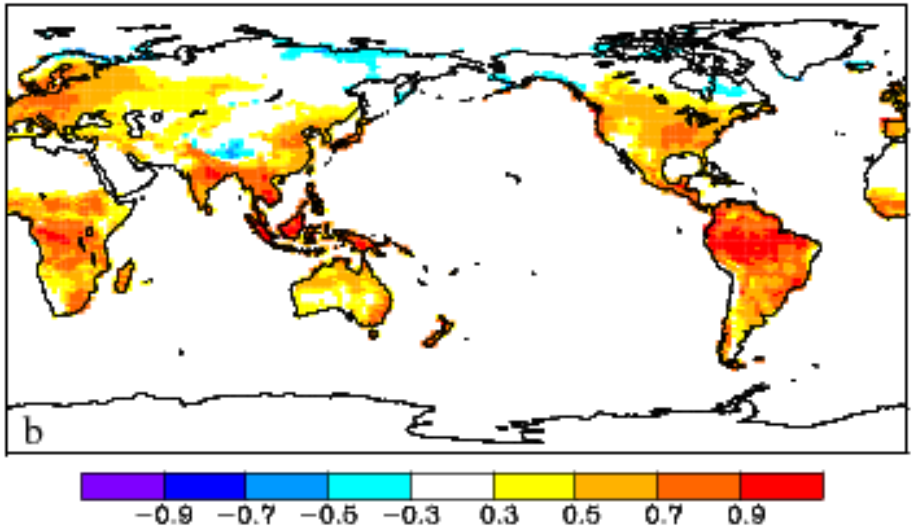
Climate drivers for interannual variability

Correlation between annual land carbon flux to the atmosphere and

precipitation



surface air temperature



Conclusions

- Simulations are generally realistic
- Improvements to target
  - Land carbon conservation when low rainfall makes sustaining vegetation difficult
  - Land carbon fluxes may be over sensitive to climate (moisture) variability
  - Excessive uptake of alkalinity in surface water → outgassing carbon
  - Underestimated export of particulate organic carbon → too much phosphate
- Carbon cycle impacted by physical model biases
  - Low rainfall biases (e.g. Indian monsoon)
  - Cold tongue bias, surface salinity biases

Thank you
